L15: Entry 2 of 7   File: PGPB   Mar 23, 2006

DOCUMENT-IDENTIFIER: US 20060064478 A1
TITLE: Geo-locating load balancing

Brief Summary Text:
[0006] Load balancing generally refers to an attempt to distribute processing
and/or communications activity evenly across a computer network so that no single
device is overwhelmed. Examples of existing load balancing methodologies include
Round-robin Domain Name System (DNS), flow-based load balancing, and Anycast
addressing. Round-robin DNS and flow-based load balancing are limited in that they
do not factor into the load balancing the location of the client or the host.
Meanwhile, Anycast addressing balances only based on network metrics, has
scalability issues, and does not ensure that traffic continues to reach the same
destination from message to subsequent message.

Description of Disclosure:
[0041] The phrase "load balancing" generally refers to a method of taking multiple
requests or processes and distributing each of them across multiple computers or
network devices. According to one embodiment the distribution among the multiple
computers or network devices is based on how busy the computer or network device is
or based on historical information regarding how previous requests or processes
were distributed among the devices.
